ABSTRACT

A new method for the synthesis of tricyclic nitrogen heterocycles from *N*,2-diallylaniline derivatives is described. These transformations proceed via sequential alkene aminopalladation of an intermediate $L_n\text{Pd}(\text{Ar})(\text{NRR}')$ species followed by alkene carbopalladation of the resulting $L_n\text{Pd}(\text{Ar})(\text{R})$ complex. Both alkene insertion steps occur in preference to C–N or C–C bond-forming reductive elimination. An unusual 1,3-palladium shift occurs when 2-Allyl-*N*-(2-vinylphenyl)aniline is employed as substrate, which yields a tetracyclic molecule with three contiguous stereocenters.

Over the past several years, our group has developed a method for the construction of nitrogen heterocycles via Pd-catalyzed carboamination reactions between aryl bromides and amines bearing pendant alkenes.¹ For example, treatment of an *N*-substituted 2-allylaniline derivative (e.g., **1**) with an aryl bromide in the presence of NaOtBu and a palladium catalyst leads to the formation of a 2-benzylindoline product (**4**).² These reactions proceed via intramolecular alkene aminopalladation of palladium(aryl)(amido) complex **2** to yield **3a**, which undergoes reductive elimination to give **4** (Scheme 1).

It seemed plausible that this method could be extended to cascade cyclization processes that yield tricyclic products if an intermediate related to **3a** could be intercepted with a

pendant alkene. For example, if *N*,2-diallylaniline were employed as a substrate, alkene aminopalladation of **2** (R

= allyl) would yield **3b**, which could undergo intramolecular carbopalladation to give **5**. Reductive elimination would then yield **6**. Overall, this transformation would generate three bonds, two rings, and two stereocenters in a single step from a simple starting material. Importantly, this method would provide a new means to access benzo-fused 1-azabicyclo[3.3.0]octanes (**6**) and related 1-azabicyclo[4.3.0]nonanes. These scaffolds are a prominent feature of several natural products³ and have also served as key intermediates in the synthesis of analogous fully saturated ring systems.⁴

The approach outlined in Scheme 1 sharply contrasts with related palladium-catalyzed cascade Heck reactions between polyalkene substrates bearing pendant alkenyl (or aryl) halides (Scheme 2).^{5–7} The Heck cascades occur through

Scheme 2. Comparison to Cascade Alkene Carbopalladation

sequential intramolecular alkene carbopalladation reactions of R-Pd-X intermediates such as **8** or **9** (X = halide or pseudohalide) and are usually terminated by β -hydride elimination from the final R-Pd-X species (**10**) to generate an alkene (**11**). Thus, elements of molecular complexity present in **10** are removed in the terminal step, as the β -elimination leads to loss of a stereocenter and an organometallic functional group. In comparison, the final step of the aminopalladation/carbopalladation cascade shown in Scheme 1 (reductive elimination from **5** to yield **6**) would produce a C–Ar bond, and the stereocenters generated in each alkene insertion step would be retained in the product.⁸

(8) To the best of our knowledge, only two reports of intermolecular cascade Heck reactions between aryl or alkenyl halides and 1,*n*-dienes have appeared in the literature. In these cases, the transformations were terminated by aryl C–H activation followed by C–C bond formation; all alkene insertion steps proceed through R-Pd-X intermediates. See: (a) Hu, Y.; Ouyang, Y.; Qu, Y.; Hu, Q.; Yao, H. *Chem. Commun.* **2009**, 4575. (b) Hu, Y.; Song, F.; Wu, F.; Cheng, D.; Wang, S. *Chem.–Eur. J.* **2008**, 14, 3110.

Although the cascade aminopalladation/carbopalladation sequence could have considerable utility, to achieve our desired transformation, we would need to overcome a significant obstacle that is not present in the cascade Heck reactions. The key intermediates in the Heck cascades (**8** and **9**) contain only a single C–Pd bond. Thus, premature termination of the cascade via competing reductive elimination from **8** or **9** cannot occur, as C–X bond forming reductive elimination from Pd(II) is thermodynamically unfavorable.⁹ In contrast, intermediate **3b** contains two Pd–C bonds and can potentially undergo competing irreversible C–C bond-forming reductive elimination to afford undesired monocyclized product **4**. In addition, the catalyst employed for the cascade cyclization must not only favor alkene insertion over reductive elimination from **3b** but also must allow the requisite reductive elimination from **5** to proceed.

In our initial experiments, we sought to find a catalyst that would facilitate the desired cascade reaction. To this end, we examined the coupling of **1** (R = allyl) with bromobenzene using catalysts generated *in situ* from mixtures of palladium acetate and phosphine ligands (Table 1). As

anticipated, these reactions afforded two major products: **12** and **13**.¹⁰ After some exploration, we discovered that bulky triaryl phosphines **14** and **15** provided **12** in acceptable chemical yields and diastereoselectivities.

(10) The formation of *N*-(prop-1-enyl)-2-methylindoline was observed in some instances. The origin of this side product is not entirely clear, but it may result from reduction or protonolysis of intermediate **3b**.

Having discovered a viable catalyst system for the cascade cyclization reaction of **1**, we proceeded to examine analogous transformations of related substrates. As illustrated in Table 2, a number of *N*,2-diallylaniline derivatives (**1**, **16**–**17**) were

converted to benzo-fused-1-azabicyclo[3.3.0]octanes **20**–**25** in moderate yields with moderate to good diastereoselectivities. Substitution at the benzylic position was tolerated, as illustrated by the conversion of **18** to **26** and **27**. The conversion of *N*-allyl-2-(but-3-enyl)aniline (**19**) to benzo-fused-1-azabicyclo[4.3.0]nonanes **28**–**29** was also achieved with moderate to good yields and selectivities. However, efforts to transform substrates bearing disubstituted alkenes have been unsuccessful. In addition, the coupling of 2-bromotoluene with **1** afforded monocyclic *N*-allyl-2-(2-methylbenzyl)indoline (**4**, Ar = 2-methylphenyl) as the major product, which was isolated in 72% yield. Only a small amount of the desired bicyclic compound was generated in this reaction.

Although most substrates examined afforded the anticipated products, reactions of **30** with aryl bromides provided surprising results (eq 1). The expected products **32a**–**c** were not obtained, but instead **31a**–**c** were generated in moderate yield with excellent diastereoselectivity.

To probe the origin of this unexpected regioisomer, we conducted three experiments with deuterium-labeled substrates **33a**–**c**. As shown in eq 2, substrates **33a** and **33b** were converted to **34a** and **34b**, with no migration of the label observed in either case. In contrast, substrate **33c**, bearing deuterium atoms on the terminal carbon of the allyl group, were transformed to **34c** with migration of a deuterium atom to the C5-methyl group.

On the basis of this data, we suggest that formation of **34c** may proceed as illustrated in Scheme 3. An initial

Scheme 3. Proposed Mechanism for Formation of **34c**

aminopalladation followed by carbopalladation could effect the conversion of **33c** to key intermediate **35** as outlined above (Scheme 1). A surprising and unprecedented 1,3-palladium/hydride shift would then yield **36**, which could undergo reductive elimination to afford **34c**. Although through-space palladium migrations have previously been observed,¹¹ only a single report has described Pd-migration from one sp³-hybridized carbon to another.¹² The conversion of **35** to **36** is particularly surprising given the fact that **35** also contains hydrogen atoms that could potentially undergo β-elimination.

(12) For rare examples of 1,5-Pd migration of alkylpalladium intermediates, which occur under oxidative conditions, see: Heumann, A.; Bäckvall, J. E. *Angew. Chem., Int. Ed. Engl.* **1985**, *24*, 207.

In conclusion, we have developed a new cascade reaction for the synthesis of polycyclic nitrogen heterocycles that proceeds by way of sequential aminopalladation and carbopalladation. These transformations illustrate that catalyst tuning can allow alkene insertion processes to occur in preference to C–N or C–C bond-forming reductive elimination in $L_nPd(Ar)(NR_2)$ or $L_nPd(Ar)(R)$ complexes. In addition, we have observed the first occurrence of 1,3-palladium migration of an alkylpalladium intermediate. Studies on the scope of this method and the application of these concepts to the development of new catalytic reactions are underway.
